Exceptions

What are exceptions ?

- Exceptions are a mechanism for handling an error during execution.

- A function can indicate that an error has occurred by throwing an exception.

- The code that deals with the exception is said to handle it.

Why use exceptions ?

- Code where the error occurs and code to deal with the error can be separated

- Exceptions can be used with constructors and other functions/operators which can not return an error code

- Properly implemented exceptions lead to better code

How to use exceptions ?

- **try**
  - Try executing some block of code
  - See if an error occurs

- **throw**
  - An error condition occurred
  - Throw an exception to report the failure

- **catch**
  - Handle an exception thrown in a try block

How exceptions work ?

- Normal program control flow is halted

  - At the point where an exception is thrown

- The program call stack "unwinds"

  - Stack frame of each function in call chain "pops"

  - Variables in each popped frame are destroyed

  - Goes until an enclosing try/catch scope is reached

- Control passes to first matching catch block

  - Can handle the exception and continue from there

  - Can free some resources and re-throw exception

What's right about exceptions

- Can't be silently ignored: if there is no applicable catch block for an exception the program terminates

- Automatically propagate across scopes (due to stack unwinding)

- Handling is out of main control flow, the code that implements the algorithm is not polluted

Exceptions syntax

C++ exceptions syntax

- Use `try-catch` blocks to catch an exception

```
try
{
    statement(s);
}
catch (ExceptionClass identifier)
{
    statement(s);
}
catch (ExceptionClass identifier)
{
    statement(s);
}
```

Place a statement(s) (function or method) that might throw an exception within a **try block**.

Appropriate code to handle the exception.

A try block **must** be followed by **one or more catch blocks**.
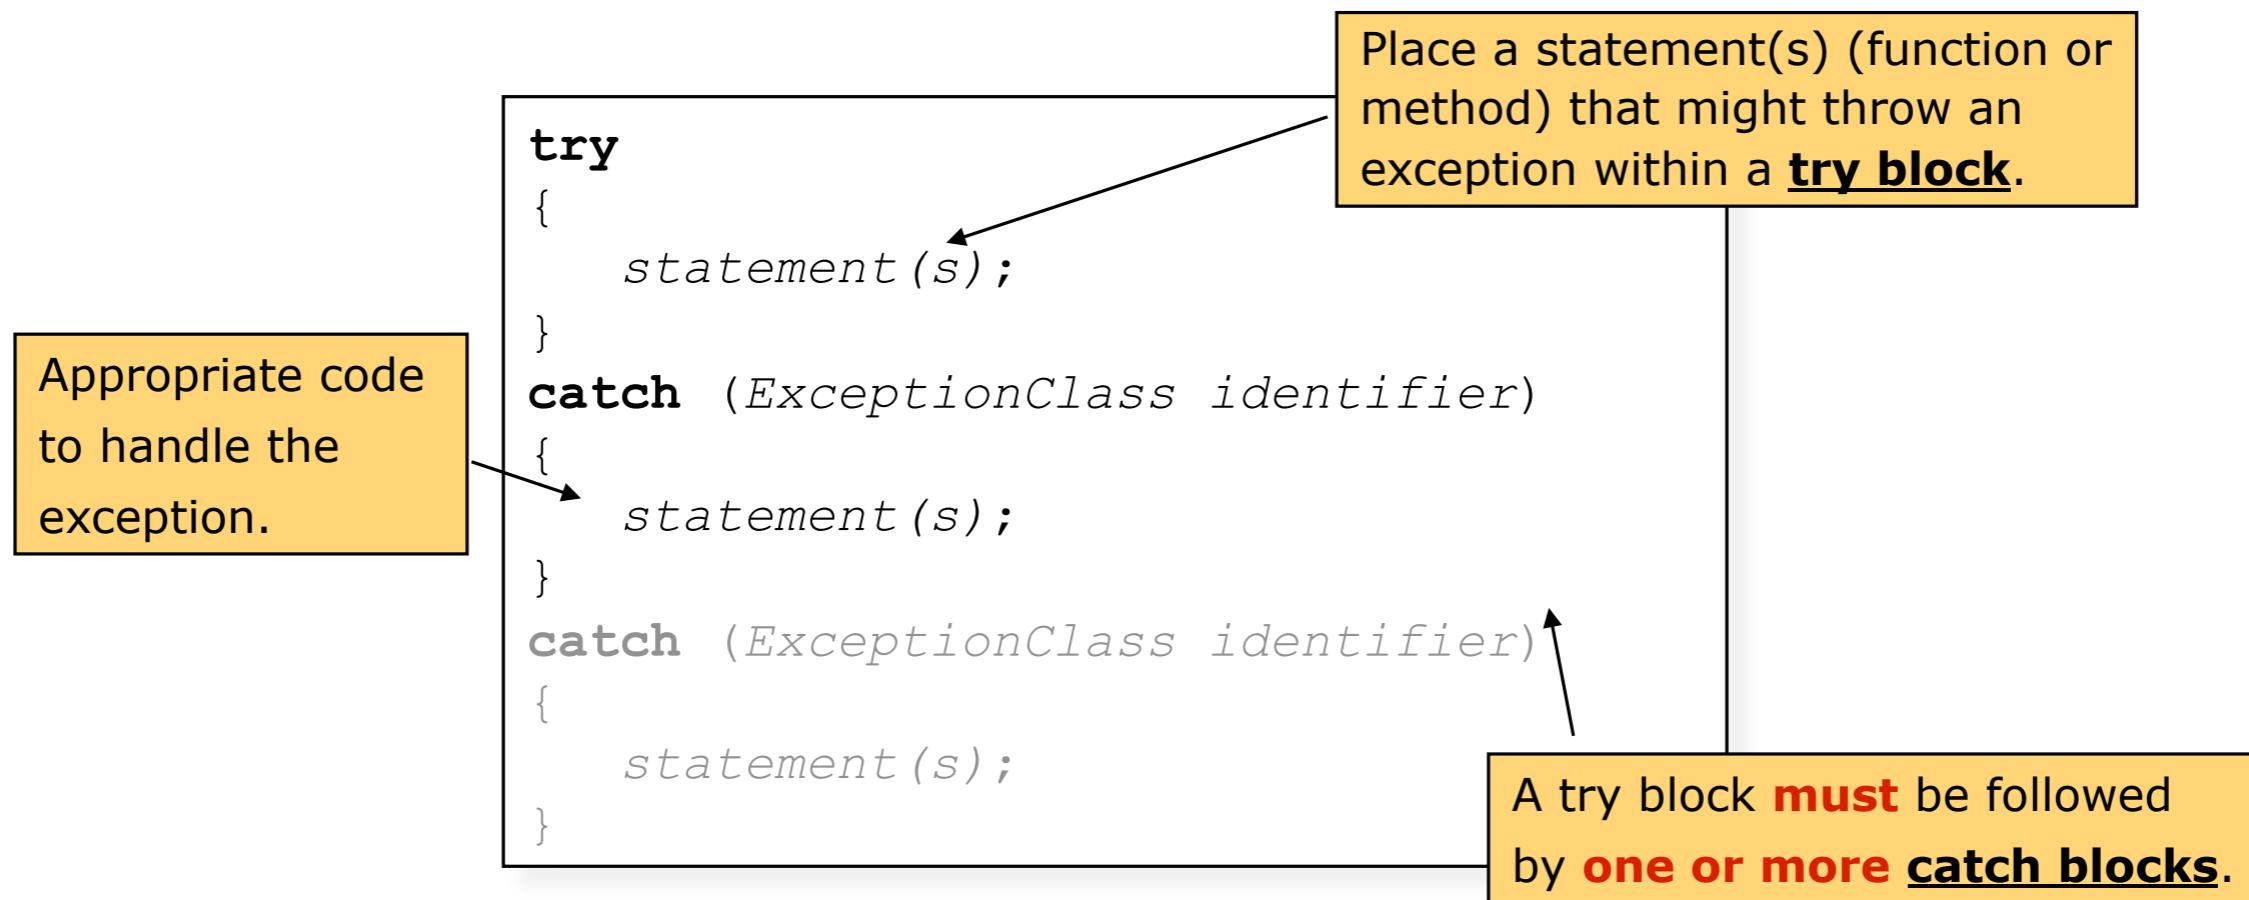

C++ exception flow

- When a statement (function or method) in a try block causes an exception:

  - Rest of try block is ignored.

  - Control passes to catch block corresponding to the exception.

  - After a catch block executes, control passes to statement after last catch block associated with the try block.

```
try
{
    …
    statement;
    …
}
catch (ExceptionClass identifier)
{
    statement(s);
}

statement(s);
```

Throw an exception
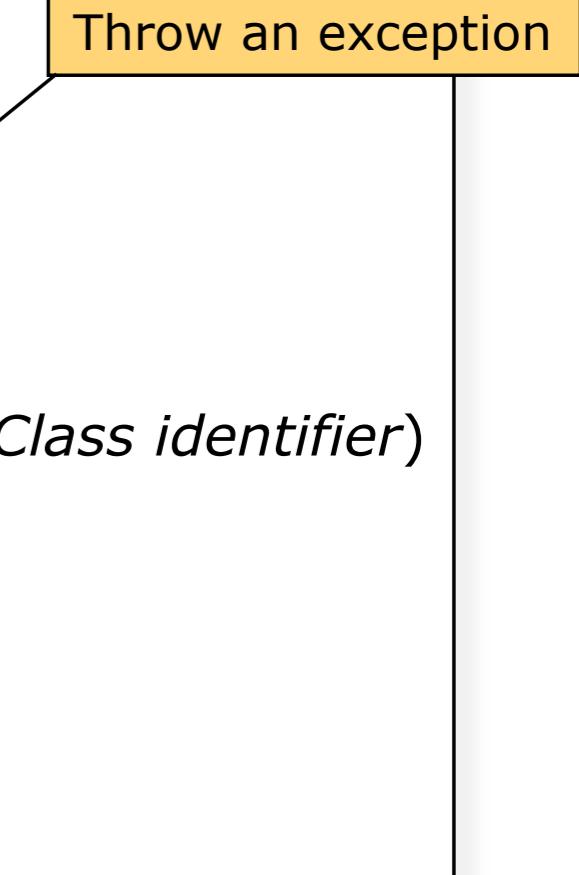

C++ exception flow - cont.

- A more complex example of exception flow:

```
void encodeChar(int i, string& str)
{
  ...
  str.replace(i, 1, 1, newChar);
}
```

Can throw the *out_of_range* exception.

```
void encodeString(int numChar, string& str)
{
  for(int i=numChar-1; i>=0; i--)
    encodeChar(i,str);
}
```

```
int main()
{
  string str1 = "NTU IM";
  encodeString(99, str1);
  return 0;
}
```

Abnormal program termination

Catching the exception

- Two examples on how to catch the exception:

```cpp
void encodeChar(int i, string& str)
{
  try
  {
     ...
     str.replace(i, 1, 1, newChar);
   } catch (out_of_range e) {
     cout << "No character at " << i << endl;
   }
}
```

```cpp
void encodeString(int numChar, string& str)
{
  for(int i=numChar-1; i>=0; i--)
    encodeChar(i,str);
}
```

```cpp
int main()
{
  string str1 = "NTU IM";
  encodeString(99, str1);
  return 0;
}
```

No character at 98
No character at 97
...

Catching the exception

- Two examples on how to catch the exception:

```cpp
void encodeChar(int i, string& str)
{
  ...
  str.replace(i, 1, 1, newChar);
}
```

```cpp
void encodeString(int numChar, string& str)
{
  try
  {
    for(int i=numChar-1; i>=0; i--)
      encodeChar(i,str);
  } catch (out_of_range e) {
    cout << "Something wrong" << endl;
  }
}
```

Something wrong

```cpp
int main()
{
  string str1 = "NTU IM";
  encodeString(99, str1);
  return 0;
}
```

Handlers

- A handler may re-throw the exception that was passed:

  - it forwards the exception

  - Use: throw; // no operand

  - after the local handler cleanup it will exit the current handler

- A handler may throw an exception of a different type

  - it translates the exception

Catching multiple exceptions

- The order of catch clauses is important:

    - Especially with inheritance-related exception classes

    - Put more specific catch blocks before more general ones

    - Put catch blocks for more derived exception classes before catch blocks for their respective base classes

- `catch(...)` catches any type

Catching multiple exceptions example

```
try {
    // can throw exceptions
} catch (Derived &d) {
    // Do something
} catch (Base &d) {
    // Do something else
} catch (...) {
    // Catch everything else
}
```

Throwing exceptions

- When you detect an error within a method, you can throw an exception by using a throw statement.

- The remaining code within the function does not execute.

- Syntax: `throw ExceptionClass(stringArgument);`

type of the exception   more detailed information

```
void myMethod(int x) throw(MyException)
{
    if (...)
        throw MyException("MyException: …");
    ...
}   // end myMethod
```

Throwing exceptions - cont.

- The exception is propagated back to the point where the function was called.

```
try
{
    ...
    myMethod(int x);
    ...
}
catch (ExceptionClass identifier)
{
    statement(s);
}
```

back to here!!
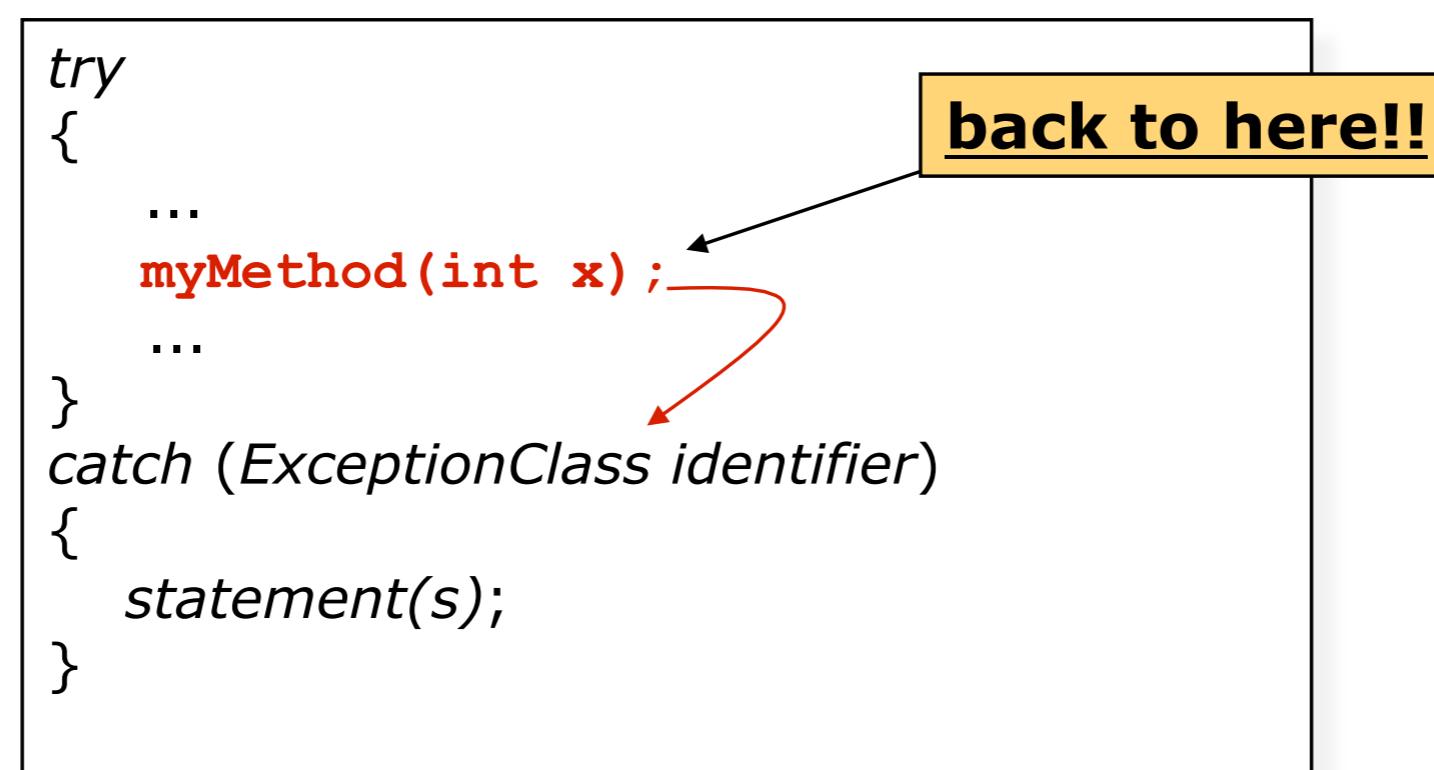

Specifying exceptions

- Functions that throw an exception have a throw clause, to restrict the exceptions that a function can throw.

  - Allow stronger type checking enforced by the compiler

  - By default, a function can throw anything it wants

- A throw clause in a function's signature

  - Limits what can be thrown

  - A promise to calling function

- A throw clause with no types

  - Says nothing will be thrown

- Can list multiple types, comma separated

Specifying exceptions examples

```cpp
// can throw anything
void Foo::bar();

// promises not to throw
void Foo::bar() throw();

// promises to only throw int
void Foo::bar() throw(int);

// throws only char or int
void Foo::bar() throw(char,int);
```

Destructors and exceptions

Destructors and exceptions

- Prevent exceptions from leaving destructors: premature program termination or undefined behaviour can result from destructors emitting exceptions

  - during the stack unwinding resulting from the processing of the exception are called the destructors of local objects, and one may trigger another exception

How to behave: example

```
class DBConnection {
public:
  //...

  // return a DBConnection object
  static DBConnection create();

  void close(); // close connection and
                //  throws exception if
                //  closing fails
};
```

```
// class to manage DBConnection
class DBConnMgr {
public:
  //...
  DBConnMgr(DBConnection dbc);
  ~DBConnMgr() {
    db.close(); // we're sure it
                //  gets closed
  }

private:
  DBConnection db;
};
```

```
// client code
{
  DBConnMgr dbc( DBConnection::create() );
  //... use DBConnection through DBConnMgr interface
} // DBConnMgr obj is automatically destroyed, calling the close
```

How to behave: example

```
class DBConnection {
public:
  //...

  // return a DBConnection object
  static DBConnection create();

  void close(); // close connection and
                // throws exception if
                // closing fails
};
```

```
// class to manage DBConnection
class DBConnMgr {
public:
  //...
  DBConnMgr(DBConnection dbc);
  ~DBConnMgr() {
    db.close(); // we're sure it
                // gets closed
  }
```

If close() throws the destructor propagates the exception

```
// client code
{
  DBConnMgr dbc( DBConnection::create() );
  //... use DBConnection through DBConnMgr interface
} // DBConnMgr obj is automatically destroyed, calling the close
```

(Not so good) solutions

- ## Terminate the program:

```
DBConnMgr::~DBConnMgr() {
  try{ db.close(); }
  catch (...) {
    // log failure and...
    std::abort();
  }
}
```

- ## Swallow the exception:

```
DBConnMgr::~DBConnMgr() {
  try{ db.close() }
  catch (...) {
    // just log the error
  }
}
```

(Not so good) solutions

- ## Terminate the program:

```
DBConnMgr::~DBConnMgr() {
  try{ db.close(); }
  catch (...) {
    // log failure and...
    std::abort();
  }
}
```

- ## Swallow the exception:

```
DBConnMgr::~DBConnMgr() {
  try{ db.close() }
  catch (...) {
    // just log the error
  }
}
```

With this solution we're hiding the problem

A better strategy

```
// class to manage DBConnection
class DBConnMgr {
public:
  //...
  DBConnMgr(DBConnectio dbc);
  void close() {
    db.close();
    closed = true;
  }
  ~DBConnMgr() { // we're sure it gets closed
    if( !closed ) {
      try {
        db.close();
      } catch (...) {
        // log and... terminate or swallow
      }
    }
  }

private:
  DBConnection db;
  bool closed;
};
```

A better strategy

```
// class to manage DBConnection
class DBConnMgr {
public:
  //...
  DBConnMgr(DBConnectio dbc);
  void close() {
    db.close();
    closed = true;
  }
  ~DBConnMgr() { // we're sure it gets closed
    if( !closed ) {
      try {
        db.close();
      } catch (...) {
        // log and... terminate or swallow
      }
    }
  }

private:
  DBConnection db;
  bool closed;
};
```

Client code should use this method...

A better strategy

```
// class to manage DBConnection
class DBConnMgr {
public:
  //...
  DBConnMgr(DBConnectio dbc);
  void close() {
    db.close();
    closed = true;
  }
  ~DBConnMgr() { // we're sure it gets closed
    if( !closed ) {
      try {
        db.close();
      } catch (...) {
        // log and... terminate or swallow
      }
    }
  }

private:
  DBConnection db;
  bool closed;
};
```

Client code should use this method...

...but if it doesn't there's the destructor

Defining exceptions classes

Syntax and example

Defining exceptions classes

- C++ Standard Library supplies a number of exception classes.

  - E.g., `exception`, `out_of_range`, … etc.

- You may also want to define your own exception class.

  - Should inherit from those pre-defined exception classes for a standardized exception working interface.

- Syntax:
  ```
  #include <stdexcept>
  using namespace std;
  ```

Defining exceptions classes

```cpp
#include <exception>
#include <string>
using namespace std;

class MyException : public exception
{
public:
    MyException(const string & Message = "")
        : exception(Message.c_str()) {}
} // end class
```

```cpp
try
{
    ...
}
catch (MyExceptoin e)
{    cout << e.what();
}
```

```cpp
throw MyException("more detailed information");
```

A full example

- An ADT List implementation using exceptions:

  - out-of-bound list index.

  - attempt to insert into a full list.

Define two exception classes

```
#include <stdexcept>
#include <string>
using namespace std;

class ListIndexOutOfRangeException : public out_of_range {
public:
   ListIndexOutOfRangeException(const string& message = "")
       : out_of_range(message.c_str()) {}
}; // end ListException

class ListException : public logic_error {
public:
   ListException(const string & message = "")
       : logic_error(message.c_str()) {}
}; // end ListException
```

Declare the throw

```
#include "MyListExceptions.h"
 . . .
class List
{
public:
    . . .
    void insert(int index, const ListItemType& newItem)

        throw(ListIndexOutOfRangeException,
            ListException);
    . . .
}  // end List
```

Method implementation

```
void List::insert(int index, const ListItemType& newItem)
    throw(ListIndexOutOfRangeException, ListException) {
    if (size >= MAX_LIST)
        throw ListException("ListException: List full on insert");
    if (index >= 1 && index <= size+1)   {
        for (int pos = size; pos >= index; --pos)
            items[translate(pos+1)] = items[translate(pos)];
        // insert new item
        items[translate(index)] = newItem;
        ++size;  // increase the size of the list by one
    } else  // index out of range
        throw ListIndexOutOfRangeException(
        "ListIndexOutOfRangeException: Bad index on insert");
}  // end insert
```

Good Programming Style with C++ Exceptions

- Don't use exceptions for normal program flow
  - Only use where normal flow isn't possible
- Don't let exceptions leave main or constructors
  - Violates "normal" initialization and termination
- Always throw some type
  - So the exception can be caught
- Use exception specifications widely
  - Helps caller know possible exceptions to catch

Exception-safe functions

- Exception-safe functions offer one of three guarantees:

  - **basic guarantee**: if an exception is thrown, everything in the program remains in a valid state

  - **strong guarantee**: if an exception is thrown, the state of the program is unchanged. The call to the function is atomic

  - **nothrow guarantee**: promise to never throw excepion: they always do what they promise. All operations on built-in types are nothrow.

Exception-safe code

- When an exception is thrown, exception safe functions:

  - leak no resource (e.g. new-ed objects, handles, etc.)

  - don't allow data structures to become corrupted (e.g. a pointer that had to point to a new object was left pointing to nowhere)
