Ing. Marco Bertini bertini@dsi.unifi.it http://www.dsi.unifi.it/~bertini/

## Coding style guidelines

"Good code is its own best documentation."

- Steve McConnell

## Why using a coding standard?

- A coding standard may help to reduce errors due to poorly written code, i.e. code that uses programming facilities in (unnecessarily) errorprone way or that expresses ideas in obscure ways
- There's no standard coding standard

## Classes and Objects

 Names representing types (i.e. classes) and namespaces must be in mixed case starting with upper case, e.g.:

Line, SavingsAccount

 Variable names must be in mixed case starting with lower case, e.g.:

line, savingsAccount

## Classes and Objects - cont.

 Bjarne Stroustrup despises this "camel" coding style and in JSF++ proposes the use of underscores, e.g.:

number\_of\_elements, Device\_driver

instead of

- numberOfElements, DeviceDriver
- Suggestion: pick whatever you like and be consistent

## Classes and Objects - cont.

- The parts of a class must be sorted public, protected and private.
- All sections must be identified explicitly.
- Not applicable sections should be left out.

## Classes and Objects - cont.

- A class should be declared in a header file and defined in a source file where the name of the files match the name of the class.
- All definitions should reside in source files.

Eclipse CDT let you decide to create the getter/setter as inline methods within the class declaration or in the .cpp file...

## Naming a variable

- The name of a variable should describe fully and accurately the entity the variable represents.
- State in words what the variable represents, probably you'll immediately see a good name.
- Do not be cryptic, do not use strange acronyms

## Naming a variable: examples

Purpose of the variable	Good name	Bad name
Current Date	currentDate	CD, current, cD
Lines per page	linesPerPage	LPP, lines, l
Running total of checks written to date	runningTotal, checksTotal, numChecks, nChecks	checks, written, checkTTL, x1

#### The 2 worst variable names

- "data" is a terrible name: every variable contains a data... a variable name should describe what data is contained
- "data2" is another terrible name, like any other variableX with X∈N
  - rethink what's the difference w.r.t.
     variable and what it should contain.
     Avoid to write code like
     if( total2 < total3)</li>

#### Variables

- Declarations shall be declared in the smallest possible scope
  - keeping initialization and use close together minimize chance of confusion;
  - letting a variable go out of scope releases its resources
- In C++ you can declare a variable wherever you want: do it!
- Initialize a variable: uninitialized variables are a common source of errors

#### Methods

 Names representing methods or functions must be verbs (followed by an object) and written in mixed case starting with lower case (like Java), e.g.:

getName(), computeTotalWidth()

 The name of the object is implicit, and should be avoided in a method name, e.g.:

```
line.getLength();// NOT:
line.getLineLength();
```

#### Methods - cont.

- Use strong verbs, not wishy-washy verbs:
  - OK: calcMonthlyRevenue()
  - NO:handleCalculation(), processInput()

#### Attributes

 Private class variables often have underscore suffix, e.g.:

```
class SomeClass {
   private:
    int length_;
};
```

 This is HIGHLY controversial. Other acceptable approaches are: underscore prefix, M\_ prefix, no suffix/prefix (use syntax highlighting of the IDE)

#### Numbers

- Avoid "magic" numbers, i.e. numbers that appear in code without being explained
- E.g.:

```
for(int i = 0; i < 255; i++)...
```

versus

for(int i = 0; i < maxEntries; i++)...

#### Numbers

 Avoid "magic" numbers, i.e. numbers that appear in code without being explained

#### • E.g.:

```
for(int i = 0; i < 255;
```

versus

Consider the case in which the number, used through the code, has to be changed...

## String

 Avoid "magic" strings as you avoid "magic" numbers. E.g.:

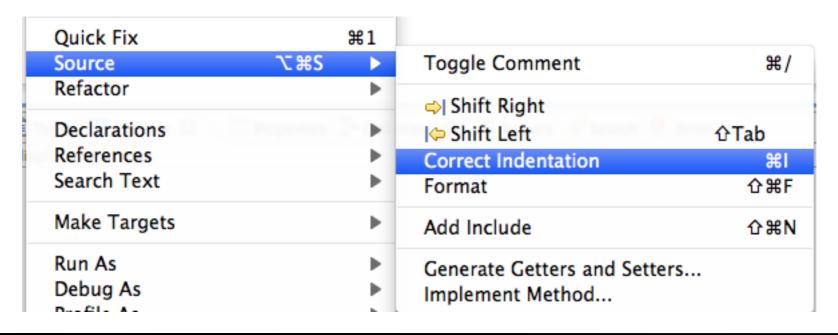

if (inputChar 
$$== '\027'$$
)...

versus

## Layout

- Indent code in a consistent manner
  - The Python language even uses indentation for grouping...
  - Editors have automatic indentation functions: use them

## Layout - cont.

 Use only one statement per line, to improve readability / debugging, e.g.:

## Layout - cont.

- Group lines in "paragraphs" using empty lines
- If there's need to split a line (some coding standards require a certain length) make it obvious and indent, e.g.:

```
totalBill = shippingCost + customerPurchase[ customerID ] +
    salesTax;
drawLine( window.North, window.South, window.East,
    window.West, currentWidth);
```

## Layout - cont.

- Group lines in "paragraphs" using empty lines
- If there's need to split a line (some coding standards require a certain length) make it obvious and indent, e.g.:

```
totalBill = shippingCost + customerPurchase[ customerID ] +
    salesTax;
drawLine( window.North, window.South, window.East,
    window.West, currentWidth);
```

+ and , signal that the statement is not complete

#### Comments

• Describe code intent, e.g.:

// get current employees info

instead of

- // update EmpRec vector
- Do not repeat the code, e.g.:

delete aVechicle; // free pointer

### Preprocessor

- Do not use macros except for source control, using #ifdef and #endif
  - macros don't obey scope and type rules and make code hard to read. All that can be done with macros can be done using C++ features
- #includes should precede all nonpreprocessor declarations
  - nobody will notice the #include in the middle of a file

#### Credits
